Invisible Cyclists? Disabled people and cycle planning – a case study of London

Abstract

This paper reports on analysis of over 50 London transport and cycling strategy documents. Both image and text were analysed, in exploring representations of disabled people, particularly as cyclists or potential cyclists. It remains unusual for disabled people’s cycling to be considered within broader transport strategy documents; instead they are overwhelmingly conceptualised as public transport users and pedestrians. By contrast it was more usual for cycling strategies to at least mention disabled people as cyclists or potential cyclists. However, discussion of policies that might increase disabled people’s participation in cycling was often limited to general aspirations or references to leisure cycling clubs and training. Few images in cycling strategies (and even less so transport strategies) showed non-standard cycles of the kind used by some disabled cyclists. Disabled people’s cycling (and barriers to cycling) needs further research and a policy approach that targets social and structural exclusion from cycling, not only individual ability and attitudes. More thought needs to be given to a range of types of disability and how these might affect cycling needs.

Invisible Cyclists? Disabled people and cycle planning – a case study of London

Introduction

Regular transport cycling is an excellent way to improve and maintain health. However, cycling take-up is frequently unequal and not all communities and groups benefit equally from use of the mode. A growing focus on cycling equity has responded to this, including disparities between groups and the barriers to cycling faced by specific groups (e.g. Cox 2016, Van der Kloof et al 2014, Winters et al 2010). Recent work has covered age, gender, ethnicity, and income/deprivation. For instance, a systematic review of English-language literature showed that women express stronger preferences than men for infrastructure separated from motor traffic (Aldred et al 2017). Infrastructure location is another area of interest: research in USA has highlighted the building of new cycle routes in more affluent, disproportionately white areas (Flanagan et al 2016).

In parallel, sociological literature has discussed the construction of the ‘cyclist’, particularly in low-cycling countries, in relation to potential exclusions (Aldred 2013). For instance, Daley and Rissel (2011) analysed how in Australia, the image of cycling as a sporty activity helps marginalise and stigmatise cyclists. Writing about London, Steinbach et al (2011) argue that dominant constructions of cycling contribute to the exclusion of female and ethnic minority Londoners, who can less easily attach themselves to discourses of cyclists as risk-takers than younger men, for instance. If in many contexts the dominant image of the cyclist is the sporty risk-taker, this stereotype may also be particularly at odds with stereotypes widely held about disabled people.

This paper brings together the two strands of literature, exploring the representation of disabled people in cycle planning language and imagery. Disabled people have been relatively little discussed in relation to cycling policy and planning (Clayton et al 2017), perhaps due to an assumption that disabled people do not cycle. Some disabled people’s advocacy groups describe cycling as itself a threat to disabled people, representing cyclists as for instance a ‘silent menace’¹. Representing disabled cyclists, groups such as Wheels for Wellbeing have suggested that many use a cycle as a mobility aid, finding cycling easier than walking, and hence deserve the recognition and protection officially granted to users of wheelchairs and mobility scooters. One problem in these debates has been a lack of data.

¹ https://www.standard.co.uk/news/london/cycle-lanes-for-undertaking-buses-8428588.html
and research on cycling (and barriers to cycling) by disabled people, and on the impact of people cycling on disabled pedestrians. This paper deals only with the former issue.

The lack of data meant the authors had to order a commissioned Census table to examine levels of commuter cycling in England and Wales among disabled people. The definition of disability used in the Census refers to activity limitation, and includes illness. One of the problems in researching this area relates to potentially differing definitions of disability, and the tendency for policy and planning to focus mainly on physical disabilities (for instance, as mentioned below ‘bus accessibility’ is in London frequently taken to refer to wheelchair accessible bus stops). Here we are maintaining an inclusive definition of disability (in England, temporary disabilities and illness are covered under disability legislation) but acknowledge that knowledge needs to be developed about the needs of all groups of disabled cyclists, not only (for example) wheelchair users.

The Census table demonstrated that disabled people do cycle to work, albeit at a lower rate than non-disabled people. For instance, in Cambridge one in four disabled people cycle to work, compared to an overall average of one in three. Among users of all modes, disabled people are 6.7% of English commuters, and 5.7% of London commuters. The graphs below illustrate (i) the proportion of users of different modes who are disabled, in England and London and (ii) London modal share for all commuters and disabled commuters.

![Figure 1: disabled people as a percentage of those using different modes to commute (Census 2011 data)](image)

The highest proportions of disabled commuters in both England and London are found within users of ‘Other methods’ (which includes for instance Demand Responsive Transport) and taxis, with the lowest proportions of disabled people (5% in England; 3.5% in London) found among those cycling to work. However, very low numbers of disabled people use ‘other’
methods and taxis to get to work. Figure 2 illustrates commute mode split for London; 
disabled Londoners, like Londoners in general, overwhelmingly use public transport or the 
car as their main mode. Cycling accounts for 3% of commutes by disabled Londoners, well 
behind other modes but used by more Londoners than taxis and ‘other’ combined (each on 
1%).

Figure 2: percentages of disabled and all commuters using different modes in London (Census data)

A new analysis of all-purpose data from the Active People Survey (Author refs removed) 
similarly shows that while in England physically disabled people are around 50% less likely 
to cycle than non-disabled people, absolute rates of cycling vary substantially. For example, 
2.3% of disabled people cycled in the past 4 weeks in the three lowest-cycling local 
authorities, compared to 21.9% in the three highest-cycling authorities. Many countries have 
little data available on disabled people and cycling, so it is hard to see where England sits 
relative to others. However, representation of other groups, such as women and older 
people, varies substantially by context, with some countries much more equal than the UK 

Therefore, while cycling rates in England are low generally, and lower among disabled 
people than non-disabled people, in English local authorities with higher levels of cycling up 
to one in four disabled people may ride regularly. This is despite a failure to recognise 
specific needs of disabled people who cycle (Clayton et al 2017). Such specific needs may 
or may not be related to use of adapted or specialist cycles. The examples below (see 
Cycling UK undated for more) illustrate the different kinds of cycles that might be used by 
people with different types of impairment. This is not intended as an exhaustive list, but to 
give a flavour of the diversity that does and could exist.
• A tandem may be used by a visually impaired rider, cycling as ‘stoker’ with sighted ‘pilot’.
• A tricycle could be used by people with balance issues, for example, people with scoliosis, who have had a stroke affecting balance, with dyspraxia², or with autism.
• Handcycles may be used by people with limited or no lower body mobility, e.g. because of paraplegia, leg amputations or arthritis.
• Some types of cycle (e.g. wheelchair cycles, cargo cycles, some side-by-side tandems) can be used by people who cannot pedal at all (by hand or foot).
• People with some mobility disability or high levels of fatigue/pain may find an e-cycle (including any of the above) suitable, as requiring lower levels of physical effort to achieve a given speed.

Not all disabled people use adapted or specialist cycles. A recent Wheels for Wellbeing survey (2017) found that among those cyclists who owned their own cycles, half owned a standard two-wheeled bicycle, with or without adaptions. Some ‘standard’ two-wheeled cycles are particularly suitable for people with more limited mobility; for example, step-through or low-step cycles. While the cycle itself (modifications and adapted cycles) has so far often been a focus, adaptations and support go beyond this. Cycle parking may not be suitable for all disabled people; either because it does not fit an adapted cycle, or because someone cannot lift their cycle if this is needed. Beyond the cycle, somewhere to park it, and (for tandem riders) a pilot or co-pedaller, other needs might relate to the provision of information in appropriate format, or to a cycling environment that is calm and easy to read. These areas remain even more under-researched than needs related to the cycle itself or to the removal of physical obstacles in the built environment.

While disabled people have historically been marginalised in cycle planning in England (Hickman 2016) there have been signs of change in London. Transport for London (TfL), the city’s transport authority, has in recent years moved to explicitly include disabled cyclists, with the concept of the ‘standard inclusive cycle’ capturing types of vehicles used by many disabled cyclists and others (e.g. people carrying children and freight). The landmark document in this regard is the second London Cycling Design Standards (LCDS), originally published in draft form for consultation in June 2014³ and adopted in revised form in December 2015. At a national level, the end of 2016 saw reference to a similar concept, the

² A common disorder affecting motor coordination: https://dyspraxiafoundation.org.uk/about-dyspraxia/
³ https://consultations.tfl.gov.uk/cycling/draft-london-cycling-design-standards/
‘Cycle Design Vehicle’ in Highways’ England’s Interim Advice Note 195, the first ever legal standard for an inclusive cycle (in relation to the Strategic Road Network).

At a national level, policy is starting to recognise the potential for disabled people to cycle. A Department for Transport report (2017) outlined eight categories that may lead to exclusion of different social groups, including disabled people, from cycling. Categories include areas where differences in (for instance) preferences, abilities, and types of trips made may be associated with indirect discrimination. This is in line with the social model of disability (Oliver 1990), where individual differences are not seen as inherently leading to social exclusion, but rather from the failure of society to plan inclusively for a range of individual characteristics. The DfT (2017) report used the categories to lay out in general terms strategies for more inclusive cycle planning; for instance, better inclusion of women may necessitate moving from a focus only on the commute, as women make a greater diversity of trip types than do men. This formed part of a wider project examining cycling potential (Lovelace et al 2017).

The eight categories of exclusion (DfT 2017) are reproduced below, but with examples and explanations used that all refer specifically to disabled people.

Table 1: Exclusions that may affect disabled cyclists and potential cyclists

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Explanations and examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Destinations</td>
<td>Disability status may affect the kinds of trips people want to make. A lower proportion of disabled adults are in work and a higher proportion of disabled people are over 60, compared with non-disabled people. Therefore focusing on commuting may exclude the potential for other utility trips made by older and disabled people.</td>
</tr>
<tr>
<td>Route quality</td>
<td>Groups under-represented in cycling (including older people, more likely to be disabled than younger people) often express a particularly high need for good quality infrastructure, separating cyclists from motor traffic. They may therefore be disproportionately excluded by having to share with high volume or high speed motor traffic. Physical attributes of adapted or specialist cycles may also mean route quality matters more: for instance, surface quality is particularly important for</td>
</tr>
</tbody>
</table>

---

4 This will be online soon.
<table>
<thead>
<tr>
<th>Route directness</th>
<th>Older people are less likely to be able or willing to cycle longer distances than younger people. Hence, if routes make detours (or unnecessarily include hills) this may disproportionately exclude older disabled people.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Obstacles</td>
<td>Many cycle routes include barriers to exclude motorcycles or other motor vehicles, include stepped access, or insist on cyclists dismounting. Some disabled cyclists are then unable to use those routes (e.g. ‘cyclists dismount’ signs do not account for disabled people who use their cycle as a mobility aid, and who may be physically unable to walk or wheel a cycle).</td>
</tr>
<tr>
<td>Discrimination and harassment</td>
<td>Disabled people have reported experiencing discrimination on public transport, street harassment, etc. While under-researched in relation to cycling, there may be analogous barriers relating to service providers (e.g. cycle hire, events) or to public attitudes and behaviour. Or conversely, cycling may make disabled people feel safer from harassment than some other modes, due to it providing greater independence and mobility (as has been anecdotally reported for women cycling, compared to walking).</td>
</tr>
</tbody>
</table>

2. The cycle and the rider

| Access to cycles | Adapted or specialist cycles and e-bikes can be expensive and few cycle shops can advise disabled people on the best cycling solutions. Disabled people may not believe they can cycle, or never have been taught to cycle, due to this belief. Some may need a tandem partner to ride. |
| Design, policy and imagery | If disabled people as cyclists are not explicitly included in policy documents and cycling promotion – both textually and in images – this may feed a belief that disabled people cannot or do not cycle. Information (such as maps) may need to be provided in a variety of accessible formats. |
| Parking | Different types of cycle have different parking needs, potentially needing both more space (e.g. three wheelers) and more security |
This paper focuses on policy discourse and imagery. While the table separates out barriers, they are inter-related. For example, if disabled cyclists remain invisible within policy documents, they are unlikely to be considered by planners. Hence environments may be designed that exclude them, such as cycle routes with sections where dismounting is necessary, meaning that those who can cycle but cannot walk are excluded. Conversely, where the cycling environment excludes disabled people, they are then likely to be under-represented among cyclists, leading to a perception among planners, policy-makers, and the public that disabled people do not cycle. The existence of a disablist environment itself can help make disabled people invisible, because of an assumption that all cyclists are able-bodied (c.f. the similar analysis in relation to wheelchair users by Gaete-Reyes 2015).

**Methods**

This paper builds on Hickman’s (2016) paper exploring images of non-standard cycles (including those used by disabled people, and those used to carry cargo or children) in five UK cycle policy and planning documents. The table below reproduces his key findings. Two of the five documents contained neither images, nor drawings of non-standard cycles. Two contained only one photograph each (out of 18 between them) of a non-standard cycle. The last one, the above-mentioned LCDS, contained relatively few photographs but a relatively large number of drawings (7) illustrating the engineering specifications (e.g. turning circles) of non-standard cycles.

Table 1. Number of images that contain cycles compared with number of images that contain cycle’s other than bicycles.
Those documents were published in 2013-4, but only one has more than one representation of a non-standard cycle, despite all having ambitions to grow and diversify cycling. Non-standard cycles matter not just for disabled people, but also because where cycling is more common, cargo cycles are widely used to transport children and goods. Getting more women cycling is likely to require – among other things – planning for cycling with and by children (Aldred et al 2017).

This article focuses on London, where arguably UK policy is most advanced in this regard. It goes beyond Hickman's work in considering imagery and language, and in analysing more documents from a longer period. This allows us to explore how discourse and imagery related to disabled people and cycling has changed, to analyse disabled people described both as cyclists and other transport users, and to compare qualitative and quantitative differences. We include both cycle planning documents and broader transport planning documents (in most cases LIPs, or Local Implementation Plans, which authorities produce at regular intervals to secure funding from TfL – if this was unavailable we looked for a transport strategy instead) from 33 London local authorities (32 boroughs and City of London).

This enables a comparison between those authorities operating in a context where the regional transport planning body, Transport for London has at least since 2014 explicitly encouraged them to consider disabled people as cyclists. We included the GLA and TfL cycling documents analysed by Hickman (Mayor’s Vision for Cycling and London Cycle Design Standards); and a second more recent document not analysed by Hickman ('Human Streets', GLA, 2016).

Our research questions are:

- How many images of non-standard cycles do cycling strategies contain (absolutely and as a proportion of all images of cycles)? How does this vary by authority and by date of publication? And how do the findings compare to Hickman’s results, which primarily focused on national-level documents?
- How do both cycling and transport strategies refer to disabled people? How many references are to disabled people as cyclists, and how many to disabled people as users of other modes? What is the nature of references of disabled people as cyclists (e.g. infrastructure design, training, etc.)?

All London boroughs were represented in the analysis, but some did not have cycling strategies available online. No cycling strategy could be obtained for Barking and Dagenham, Barnet, Bexley, Camden, Enfield, Havering, Hillingdon, Hounslow, Kensington
and Chelsea, Lewisham, Merton, or Newham. Transport strategies were available from 
borough websites for all boroughs. The list below illustrates what was available and 
analysed. Boroughs for which a cycling strategy was available had on average around 
double the 2011 Census cycling rate of those that did not (5.3% vs. 2.8%). Thus those 
boroughs with available cycling strategies were likely in general to be those with higher 
levels of cycling. One exception was Camden, with 7.1% cycling to work but no separate 
cycling strategy\(^5\).

Images were identified manually, by reading through all the strategies in question and 
counting those depicting standard versus non-standard cycles. By ‘image’ what is meant 
here is any kind of visual depiction: a photo, symbol, drawing, picture or sketch. Photos were 
by far the most common type of image. ‘Non-standard’ cycle refers to any cycle other than a 
standard two-wheeled bicycle, which could be (but is not limited to) a tricycle, handcycle, 
tandem, recumbent or cargo bike.

Generally, each image was counted as ‘one’ (i.e. in some photos more than one cycle, or a 
group of cycles, were depicted, but for simplicity that image would just be counted as ‘one 
image’ of a cycle, rather than the 6 or 7 that might have been shown). Therefore, because 
many images were of this nature (i.e. clusters or groups of cycles) and tended to 
overwhelmingly depict standard two-wheeled bicycles, the under-representation of non-
standard cycles might be greater than stated. Efforts were made to ensure that duplicate 
images within a document were not counted. Similarly, images were not counted where it 
was impossible to tell what kind of cycle(s) were being depicted (usually this was the case 
with images containing a crowded group of cycles, or an image showing only part of a cycle). 
Of images depicting non-standard cycles, many were of cargo bikes and featured parents 
with children, and so again the findings may not reveal the extent of under-representation 
specifically of disabled cyclists.

The textual analysis proceeded differently; using NVivo to code and then analyse material. 
Firstly, material was automatically coded that referred to a wider range of terms that might 
be associated with disability, using the following stemmed NVivo search:

\[\text{Disabled OR Disability OR Inclusive OR Ability OR Impairment OR Blind OR Deaf OR Wheelchair OR Accessible OR Mobility}\]

\(^5\text{Arguably authorities should not need separate cycling strategies, walking strategies and so on if transport were truly integrated – in practice however, such strategies may well be useful in redressing the traditional prioritisation of motorised transport in the UK.}\)
The terms were kept broad given the ambiguous nature of language. For instance, ‘accessibility’ is sometimes used to refer to the specific needs of disabled people, and sometimes to refer to general ease of access (e.g. bus stops located near homes – which itself may exclude disabled people, if assumptions are made about walking speeds). Manual coding was then used, removing irrelevant material and coding sub-themes relevant to the research question and emerging from the data, e.g. references to specific forms of transport. Analysis included quantitative elements (e.g. counting types of reference by year of publication) and more qualitative elements (e.g. coding types of intervention referred to, and analysing these in the context of broader cycling discourses).
Results

About the strategies

The oldest documents dated from 2004, with the most recent from 2016. Below we present the dates by type of document; transport or cycling strategy, for all documents (i.e. including the GLA and TfL documents).

![Date by document type, borough and GLA/TfL documents](image)

**Figure 4: dates of reviewed documents**

A peak in 2011 relates to the publication in 2011 of 24 documents, almost all LIPs. This relates to the LIP cycle which is more structured (led by TfL) than is the production of cycling strategy documents. Cycling strategy documents are largely more recent; the year in which most were published being 2015. We might expect documents published between 2014 and 2016 to take more account of inclusive cycling, given the publication in 2013 of the GLA’s *Mayor’s Vision for Cycling* and in 2014 of TfL’s *London Cycling Design Standards*, both seen broadly as heralding a new approach aiming to diversify cycling.

Imagery

The 56 documents reviewed contained a total of 364 images of cycles. Of these, 13 (or 3.6%) were non-standard. Some documents, particularly transport strategies, contained no or very few images of cycles or people cycling. The table below contains only those documents with 5 or more images of cycles, and the numbers and proportion of these that were non-standard.

---

6 Of documents with 1-4 images of cycles, none portrayed any non-standard cycles.

There are only four documents containing any images of non-standard cycles. TfL’s *London Cycling Design Standards* (2014), a relatively visual document (being guidance for planners and engineers) contains ten, while the first GLA document (*Mayor’s Vision for Cycling*, 2013), Waltham Forest’s cycling strategy and Harrow’s cycling strategy all contain one image each. Brent, Ealing and Kingston all show no non-standard cycles, despite each containing images of at least ten cycles. No LIP/transport strategy documents showed any images of non-standard cycles.

All four documents containing such images were published between 2013-5. However, of the eight that failed to show such images, six were published in 2013 onwards, one in 2011 and one in 2010. Hence while it is only since 2013 that such images appear at all, there are still many documents that fail to include them; even among those with five or more images of cycles. Non-standard cycles are not reached for when an image of ‘a cyclist’ or ‘a bike’ is needed; where documents have few images the norm is still always for these to be
‘bicycles’. For instance the two documents from Hackney, published in 2015 in the highest-cycling borough in London, contain between them three images of cycles, all bicycles.

Language and Discourse

Analysis Challenges

References to disabled people and cycling were at times surprisingly difficult to identify. The reason for this is discursive, and relates to a couple of concepts used to discuss disabled people, cycling, and transport. The first is the concept of ‘accessibility’. This is at times used specifically to discuss changes made to ensure disabled people can access transport services; for example, Transport for London’s ‘bus stop accessibility programme’, which aims to ensure that 100% of bus stops can be accessed by wheelchair users.

At other times, ‘accessibility’ is used as a general term for ease of getting to places. For instance, Greenwich LIP defines it as meaning ‘how easy it is for people to get to places, jobs, homes and services.’ Complicating matters further, a general definition of accessibility may obscure the needs of disabled people; for instance, if accessibility is defined as access to public transport within a specific distance/time (as with TfL’s PTAL, Public Transport Accessibility Level, measure) this may exclude those who take longer to walk that distance. In addition, at times accessibility is used in completely different ways, for instance Newham used it at least once to refer to the ability of people of all faiths to access a site.

Therefore, reference to ‘accessible cycle parking’, for instance, does not necessarily mean cycle parking that can be used by disabled people using non-standard cycles. At times, it may simply mean cycle parking within a development which can be relatively easily accessed by residents (e.g. not further away than car parking). If designers have forgotten that disabled people might cycle, such parking could in fact end up not being accessible for disabled people (for instance, if a lift is too small to fit in adapted cycles). In many cases reading the document or surrounding text was necessary to make a judgement call on whether the reference was about disabled people.

A second problem relates to the concept of ‘ability’. ‘All-ability’ is sometimes used as a term specifically to include disabled people; as in many strategies referring to ‘all-ability’ cycling clubs run by organisations such as Wheels for Wellbeing, Pedal Power and Bikeworks. Not all such organisations make much use of the ‘all ability’ term; instead some refer to ‘inclusive’ clubs and reference disabled people, in Pedal Power’s case teenagers and adults with learning disabilities. However, while ‘ability’ sometimes seems to be a reference to having (or not) a disability, it is also used in documents to refer to cycling ability. If these
were conflated it could incorrectly imply that disabled people in general have lower cycling abilities than non-disabled people.

This second problem is deepened by the individualised tradition of cycling policy in the UK, in which the unwillingness or inability to cycle in current conditions was interpreted as due to a lack of cycling ability or confidence (Aldred, 2012). This could be analogised to the medical model of disability, in which an individual's impairment rather than an exclusive environment is blamed for the problems they experience (Oliver, 1990). The following extract from Islington’s LIP illustrates the approach; as well as not being clear whether it specifically relates to cycle training inclusive of disabled people, or just cycle training for those with lower cycling abilities.

*The council will continue to offer free cycle training courses to all residents, employees and students based in Islington. The training offered is a proficiency test, delivered by accredited instructors, that aims to improve cycle skills for all abilities. Cycle training is an important tool in getting more people to cycle, improving skills and improving road safety. Cyclists who are confident and proficient are more likely to cycle more often and less likely to become involved in a road traffic accident.*

Similarly the comment below, from Hammersmith LIP, talks of ‘all ability cycle training’ but the following phase suggests that this is aimed at stopping those with poor cycling skills or low confidence (rather than disabled people) riding on footways.

*All ability cycle training will give cyclists the skills, knowledge and confidence to ride on roads rather than footways.*

**Disabled People in Cycling and Transport Strategies**

As indicated above, categorising references to disabled people in these documents was not always straightforward. It was perhaps particularly challenging for cycling, but also problematic for other modes. For instance ‘accessible stations’ did not always refer to making provision for disabled customers, but sometimes to, for example, opening up more station entrances for people to use. In many cases judgement had to be used; drawing upon expert knowledge of changes perceived to be aimed at benefitting disabled users (for instance, reference to inclusive streetscape alongside tactile paving and decluttering; or specific funded programmes such as the TfL Accessible Bus Stops Programme). On the other hand, frequently there were general references to disabled people as important transport users but without giving details of precisely what modes were to be considered or what policies were envisaged.
Of the 24 cycling strategies analysed (21 from London Boroughs, plus one from TfL and two from GLA), only 17 (71%) referred to disabled people, whether as cyclists or not. By contrast, almost all (32/33; Tower Hamlets being the only exception) transport strategies referred to disabled people in some respect. The number of references per source varied from 0 to 96, with a mean of 17 and a median of 11 references per source. Some consideration of disabled people at least therefore seems usual in such documents, although to a lesser extent within cycling strategies.

**Disabled People as Cyclists**

The analysis that follows necessarily involves some interpretation as to what is, and what is not a representation of disabled people as cyclists. We restrict this to references that seem specific either in directly referencing disabled people, or changes that are clearly aimed at making cycling more accessible for disabled people (e.g. in TfL LCDS references to parking for tandems and cargo cycles). Thus, general references to ‘accessibility’ and ‘inclusion’ and to ‘all ability’, unless other information makes this clear that it is about disabled people have been excluded. The table below contains all these ‘definite’ references, and a classification of them in terms of policy (e.g. is the suggested policy response about design? About training? About events?)

**Numbers of references to disabled people as cyclists**

Twenty-one of the other fifty-seven documents (37%) made some reference to disabled people as cycle users. This was largely found within cycling strategies – 13 documents making such references were cycling strategies, compared to 8 which were LIPs or transport strategies.

It makes sense to separate pre-2014 from the 2014-6 period, as 2014 was when the draft LCDS was published, with its extensive coverage of non-standard cycles. Between 2004-13, four of ten (40%) cycling strategies mentioned disabled people as cycle users, and six did not. Conversely, between 2014-16, nine of fourteen (64%) did, while five did not. Thus it became more usual for cycling strategies to at least mention disabled people as cycle users, although still (in the 2014-6 period) this is far from universal, with around a third of such documents making no mention of disabled cyclists. For example, transport or cycling strategies produced by the London Boroughs of Bromley, Hackney, Harrow, and Wandsworth in 2015-6 made no mention of disabled people as cyclists.

The picture is less encouraging for transport strategies. Only five of the sample documents were published in 2014-6, but only one of these (20%) made mention of disabled cyclists, compared to seven out of the twenty-eight (25%) strategies published in earlier years.
Content of references to disabled people as cyclists

Where disabled people were referred to as cyclists, what does this mean? Broadly speaking, most references fell into several different categories. There was aspiration, where a local authority described a desired future in which disabled people (and others) happily cycle, but no specific means of achieving this was outlined, even in general terms. There was design, into which all London Cycle Design Standards references fell – where accessible design of routes, parking facilities, etc. was referenced. There was training and clubs, where documents spoke of getting disabled people to undertake cycle training or to attend cycling events. Finally, references were made to promoting cycling among disabled people.

Firstly, we removed references found in LCDS as they were characteristic of a design guide, and rather different to the borough strategies (and the two GLA documents). Indeed, 16 references to disabled cyclists were found in LCDS alone, compared to 40 across all other documents. The LCDS provides very detailed guidance alongside general principles on inclusive design and the concept of the ‘standard inclusive cycle’. The table below illustrates the numbers of references to each category in other documents (two fell into more than one), with examples of each.

Table 3: themes used to discuss disabled people’s cycling

<table>
<thead>
<tr>
<th>Category</th>
<th>Number of references</th>
<th>Sources covered</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aspirational – general references to more disabled people cycling as desirable.</td>
<td>7</td>
<td>Brent, Hammersmith, Haringey, Harrow (two), Kingston and Tower Hamlets cycling strategies</td>
<td>‘Cycling is an activity for all regardless of age, gender, disability and ethnicity’ (Brent)</td>
</tr>
<tr>
<td>Clubs – specialist sports and leisure clubs for disabled cyclists.</td>
<td>8</td>
<td>Hackney cycling strategy (two), Kensington LIP (three), Lambeth cycling strategy, Tower Hamlets cycling strategy (two)</td>
<td>‘More actively promote Bikeworks ‘All Ability Cycling Club’ based from Victoria Park and Pedal Power based in Finsbury Park.’ (Hackney)</td>
</tr>
<tr>
<td>Design – including references to removing obstacles, inclusive cycle</td>
<td>14</td>
<td>Croydon cycling strategy, Hammersmith LIP (two), Haringey cycling strategy, Kingston LIP, Lambeth cycling strategy,</td>
<td>‘Design infrastructure, including parking, to accommodate different designs of cycles.’ (Southwark)</td>
</tr>
</tbody>
</table>
Strategies differed widely in tone and content. For instance, Tower Hamlets Cycling Strategy, Hackney Cycling Strategy, and Kensington LIP only made references to disabled people and cycling in clubs, suggesting that it is not seen as a mode of transport for disabled people, but rather a leisure activity. Southwark and Waltham Forest Cycling Strategies specifically highlight cycling as a transport mode for disabled people, referring both to design and promotion. Other strategies are more aspirational in tone. Harrow’s strategy contains two aspirational statements, but in terms of suggested policies and interventions, this is followed only by one reference to training:

> ‘Creating the right environment for children to cycle safely will also make it easier for us to widen the demographic of cyclists to include more women, people from minority ethnic groups, older people and disabled people for whom the bicycle can bring greater freedom...’
Cycling should be seen as an enjoyable, safe, practical and accessible everyday option for more people, including older and people with disabilities, children and families. [...] The Council will provide cycle training for adults and children and for people with disabilities to create a confident and responsible cycling community in the Borough.'

To what extent are different dimensions of inequality dealt with in the strategies? Of course, not all may apply, but this gives a sense of how these documents (and presumably, policymakers involved) understand barriers to disabled people cycling. The table below re-analyses the material from cycling strategies to identify whether they cover the different dimensions of exclusion (from DfT 2017). In some cases it is difficult to identify whether the dimensions are covered and this is noted below (for this reason we also do not separate references and sources covered).

Table 4: barriers to disabled people's cycling participation covered in the cycling and transport strategies

<table>
<thead>
<tr>
<th>Dimension</th>
<th>References</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. The environment and the rider</td>
<td>Destinations No explicit discussion of whether/how disabled people's trip destinations/origins might vary from non-disabled people's trips. In terms of trip purposes of disabled cyclists, eight references are made to leisure cycling clubs, one to cycling as a leisure activity, and one to cycling to school.</td>
<td>'We also want to encourage cycling amongst disabled people – cycling is the second most popular activity (after swimming) for disabled people, but often requires specially adapted bikes.' (Hammersmith).</td>
</tr>
<tr>
<td></td>
<td>Route quality No references to high quality routes being needed by disabled cyclists. However, six references are made to designs that accommodate specific needs of disabled cyclists (e.g. related to width of adapted cycles, or to accessible crossings).</td>
<td>'All facilities should be able to accommodate hand bikes, trikes and other none standard cycles.' (Croydon).</td>
</tr>
<tr>
<td></td>
<td>Route directness No mention of the importance of route directness specifically for disabled cyclists.</td>
<td>N/A</td>
</tr>
<tr>
<td>Obstacles</td>
<td>Nine references, although not all specifically referenced disabled cyclists.</td>
<td>‘Physical barriers will be removed such as railings and kerbs in order to provide convenient local access by bicycle, especially through estates.’ (Lambeth)</td>
</tr>
<tr>
<td>-----------------------------------------</td>
<td>---------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Discrimination and harassment</td>
<td>No mention of this as a possible barrier.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

2. The cycle and the rider

<table>
<thead>
<tr>
<th>Access to cycles</th>
<th>The eight references to leisure cycling clubs cover providing access to specialist cycles, while there are two additional references to the need for adapted/specialist cycles. Nine references to training to ensure disabled people can cycle.</th>
<th>‘we will empower more residents with disabilities to cycle through more structured provision of opportunities for all ability cycling (e.g. adapted bike loan)’ (Waltham Forest)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Design, policy and imagery</td>
<td>No document sets out a need to depict disabled cyclists and/or adapted cycles within, for instance, broader transport policy communications.</td>
<td>N/A</td>
</tr>
<tr>
<td>Parking</td>
<td>Three (possibly more depending on the meaning of ‘infrastructure’).</td>
<td>‘Design infrastructure, including parking, to accommodate different designs of cycles’ (Southwark)</td>
</tr>
</tbody>
</table>

While most transport strategies still fail to discuss disabled people as cyclists at all, some cycling strategies clearly do better, especially around using clubs to provide access to adapted/specialist cycles, removing obstacles on cycle routes, and to a lesser extent recommending infrastructure accommodating different types of cycle or the specific needs of disabled cyclists. However, the coverage is still often relatively limited, with general aspirations towards inclusivity often not accompanied by more specific identification of barriers to be tackled. Southwark and Waltham Forest, recent and relatively comprehensive examples, have clear aspirations to change design to be more inclusive. Southwark
additionally lists policies that should be followed to achieve this, while Waltham Forest refers to bicycle access, parking, and inclusive on-street design. In general, however, even the most comprehensive examples lack discussion of how different types of disability might imply different policy and planning changes. This points to the relative lack of knowledge in the area and the assumption, perhaps, that most disabled cyclists are physically disabled.

No strategies include recommendations about route directness as particularly important for disabled cyclists, none mention the need to counter discrimination or harassment of disabled cyclists, and none recommend use of images of disabled cyclists and adapted cycles within other documents. Further, discussion of destinations is generally implicit; there seems often to be an assumption that disabled people are more interested in leisure than utility cycling but (while it might be the case for older disabled people no longer in paid work, for instance) this is not explicitly stated nor justified. While the use of adapted/specialist cycles by some disabled people is discussed, this is usually in the context of leisure clubs offering such bikes, and less often in the context of transport authorities facilitating everyday access to such cycles, or providing suitable cycle parking.

**Disabled People as Users of Other Modes in transport strategies**

How does coverage of disabled people as cyclists compare with users of other modes? In the transport strategy documents, the figure below shows how many of the 33 strategies referred to disabled people as users of different modes.

![Bar chart showing the percentage of strategies mentioning disabled people for different modes: Cycle, Taxis, Car, Demand responsive transport, Pedestrians, Unspecified, Public transport.]

*Figure 5: sources referring to disabled people as users of different modes in transport strategies*
‘Unspecified’ refers to general statements about supporting the mobility of disabled people. While very common (30/33 documents) this was exceeded by 32/33 documents referring to disabled people as public transport users. Many documents spoke of funded programmes to overcome barriers to disabled people using public transport, such as TfL’s Bus Stop Accessibility and Station Accessibility programmes. Indicators were referred to, primarily the percentage of bus stops accessible to people with mobility impairments, but also (for example) numbers of stations with step free access. Almost as common were references to disabled people as pedestrians (29/33 documents), with references to streetscape programmes seeking to remove clutter, install tactile paving, and so on. Less common (19 and 18/33 documents) were references to demand responsive transport and car use (and related policies such as provision of disabled car parking) with references to cycling least common (8/33 documents).

The chart below illustrates the contrasting numbers of references within the sources, to the different modes (‘unspecified’ removed):

![Chart showing references to disabled people as users of different modes, within transport strategies]

Figure 6: references to disabled people as users of different modes in transport strategies

References to public transport are now clearly dominant, compared to pedestrians. Although a similar number of documents discuss disabled people as car and DRT (demand responsive transport) users, there are well over twice as many references to car users, compared to DRT users.

An example of disabled people being considered as transport users but not as cyclists can be found in the Bromley LIP (2014:47). The text illustrates the identification of the Equality Act duty towards disabled people, and defines them as public transport users,
pedestrians/footway users, and car users, but not cycle users (there are no references to
disabled cyclists in the document, nor in the borough's Cycling Strategy).

Emphasis is our own, to highlight the different modes covered.

The Council has a duty to promote equality for people with a disability. In terms of transport,
the Council will continue to engage with organisations representing disabled people when
preparing schemes.

We will also: • Continue to improve access to bus services by ensuring that buses can
approach the kerb closely enough to use their access ramps. • Work to improve or adapt
conditions in the footway, and to ensure unobstructed level access to bus stops as our work
programmes progress. • Work with the rail industry to co-ordinate improved access in the
highway with improved access within the railway estate, for example when lifts or ramps are
provided at stations. • Continue to identify and act on the need for on-street disabled [car]
parking spaces.

Discussion

Disabled people as cyclists are still rarely encountered within London transport strategy
documents. They are somewhat more present in cycling strategies, albeit only just over half
the cycling strategies we analysed contained reference to disabled cyclists, barriers they
face or changes that might be made to facilitate their cycling. Only one document, London
Cycling Design Standards, referred explicitly to Britain’s Equality Act in this regard, although
this places duties on public authorities to ensure equal access, including to transport
services and the street environment.

Narratives around disabled cyclists are still, in the main, relatively under-developed. For
instance three strategies (two cycling, one transport strategy) refer only to disabled cyclists
in the context of clubs. We are not suggesting that such clubs (and recreational cycling more
broadly) are not important. However, an exclusive or majority focus on clubs suggests a view
that disabled people are only recreational and not utility cyclists. It further suggests the
authorities in question are perhaps not aware of design barriers to utility cycling on the
highway by disabled people, which they may have the power to mitigate. These might
include obstacles, narrow cycle tracks, and traditional cycle parking that does not
accommodate larger cycles.

Findings relating to references made to disabled people as users of different modes
suggests that London’s transport authorities still fail to see disabled people as current or
potential cyclists, often with specific accessibility needs. This could have a negative impact
on the ability of authorities to deliver fully inclusive cycling infrastructure. Moreover, 30% of
cycling strategies failed to mention disabled people at all, either as cyclists or non-cyclists
potentially affected by cycling or by cycling infrastructure.

As public bodies, London’s local authorities are required by the Public Sector Equality Duty
(PSED) to ensure that they consider the needs of all individuals in their day-to-day work.\(^7\)
The function of the PSED is to help public bodies consider how different people will be
affected by their activities and to make sure that this forms part of their policy and decision-
making processes. None of the documents audited were directly or specifically related to
disabled people or disability issues, and could well be pieces of work seeking to discuss
transport or cycling policy in a general sense. Some were short and no more than a dozen
pages, leaving little room for detail (while others were more than a hundred pages). Yet,
what these findings reveal is a probable lack of awareness of the needs of disabled people
as cyclists and the ways in which infrastructure and policy may create and reinforce barriers
to disabled people’s cycling.

**Conclusion**
Finally, we conclude with some thoughts on further research and policy implications. We
need more analysis and better data on disabled people’s cycling and barriers to take-up and
continuation; not just in London or England but in other cities and countries where data and
research are often limited (Clayton et al 2017). This might be conducted through new
academic or government-led research projects, or through secondary analysis of existing
datasets, such as in England the Active People Survey/Active Lives Survey or National
Travel Survey. Studies should also develop knowledge about how different types of disability
impact on cycling needs, considering physical, mental, and developmental disabilities. New
research could usefully examine how different high and low-cycling contexts vary in the
discourse and imagery that they use around cycling and disabled people.

While this study only covered London, there are implications for other cities and countries,
as they seek to diversify cycling. New concepts and the promotion of inclusive approaches at
the top (e.g. in the TfL LCDS, and in the Highways England IAN) need to feed into
monitoring and change at a local level. In London transport strategies, requirements to report
on bus stop accessibility, and the availability of a Bus Stop Accessibility programme with
funding attached, seemed to have helped increase awareness that disabled people (or at
least wheelchair users) face barriers to bus use, and that this could be changed through

(accessed 31/08/16).
design. In London and elsewhere, measuring inclusiveness and accessibility of cycle routes could be a first step towards providing targets for improvement and funding to help authorities make changes. A broader ongoing policy shift (Aldred et al 2017) from seeing individual cycling ability as determining cycling participation, and towards addressing structural and social barriers to cycling, should also help disabled cyclists although their needs will have to be explicitly considered.

We would suggest measures to improve the overall visibility of disabled cyclists through imagery and language, which can be a quick (and inexpensive) win for those involved in cycling policy. By increasing the visible representation of disabled cyclists in cycling and transport policy documents – in a way that is both meaningful and relevant – those responsible for planning and implementing cycling policy will not only be enhancing their own understanding of their responsibility towards disabled cyclists, but will be actively encouraging more disabled people to take up cycling. The more images of non-standard cycles made available and in circulation, the more likely it is that a disabled person will come across them and be encouraged to discover more. The same principle can be applied to an increased number of references made to disabled people as cyclists. This could be supported by the creation of national image banks that can easily be used by authorities putting together transport and cycling strategies.
